Title: PROCESSING IMAGE DATA

CERTIFICATE OF MAILING UNDER 37 CFR 1.10

'Express Mail' mailing label number: EV 887 247 188 US

Date of Deposit: January 29, 2008

I hereby certify that this paper or fee is being deposited with the United States Postal Service 'Express Mail Post Office To Addressee' service under 37 CFR 1.10 and is addressed to: , P.O. Box 1450, Alexandria, VA 22313-1450.

By: 

Name: Kathleen Krochko

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

We are transmitting herewith the attached:

- ☒ Transmittal sheet, in duplicate, containing a Certificate of Mailing under 37 CFR 1.10.
- ☒ Certified copy of United Kingdom application No. GB 02 16844.1, filed July 19, 2002, the right of priority of which is claimed under 35 U.S.C. 119.
- ☒ Return postcard.

Please consider this a PETITION FOR EXTENSION OF TIME for a sufficient number of months to enter these papers, if appropriate.

Please charge all fees to Deposit Account No. 50-0494 of Gates & Cooper LLP. A duplicate of this paper is enclosed.

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation and Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents originally filed in connection with patent application GB0216844.1 filed on 19 July 2002, together with the Statement of inventorship and of right to grant of a Patent (Form 7), which was subsequently filed.

I also certify that the attached copy of the request for grant of a Patent (Form 1) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 2006 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Editing Image Data

Background of the Invention

1. Field of the Invention

5 The present invention relates to a method and apparatus for processing image data, wherein components of said image data are defined by structured data processing nodes, which require editing.

2. Description of the Related Art

10 Many post production processes have been devised and employed over the years to enhance movie productions or video films with what is commonly referred to as "special effects". Such image enhancement have long been provided by means of using dedicated hardware, either as a scale model to be filmed and subsequently composited in post production
15 or, more recently, by means of effects generators such as computer apparatus configured to output rendered image components to be also subsequently composited.

 Technical advances in image processing systems have enabled the generalisation of the "blue screen" technique in video environments and
20 "green screen" technique in cinematographic environments, whereby actors are filmed in a studio configured with blue or green saturated surroundings in order to generate a clip of foreground image frames. An alternative clip of background image frames is subsequently generated and a compositing process allows an editor to seamlessly blend the foreground and
25 background image frames by means of keying part of the corresponding video signals, for instance the luminance or chrominance signal.

A problem inherent to the above image processing techniques was that effects generation could not take place in real-time, that is all of the various components in each image frame within a clip of such image frames would have to be shot in the case of real actors and/or situations committed to cinematographic film, or rendered in the case of computer graphics images, prior to the compositing process. Thus, if the appearance of any of such image components was artistically unsatisfactory, the only possible manner of remedying this problem would be to do another shot on new cinematographic film or amend parameters in the computer to generate a new version of the computer-rendered image components.

Modern image processing systems overcome the above problem by means of providing real-time image data processing capability, whereby every image component within an image frame exists as a hierarchical sub-structure of data processing nodes within a main structure, which thus defines the entire image frame. An image editor using such a modern image processing system can amend parameters and/or data in any of said data processing nodes to aesthetically improve any image component within an image frame and assess the effectiveness of his editing in real-time.

An important problem has however developed within modern image processing systems as described above, as the size of modern movie image frames or high definition video image frames has dramatically increased both in resolution and in the number of components therein, to such an extent that it has now become impractical to display one such image frame at full resolution, its corresponding structure of data processing nodes and further user-operable controls to edit the data and/or

parameters of said nodes in said image processing systems. Indeed, conventional display devices of image processing systems can barely accommodate such image frames at full resolution, often as not exceeding 2000 pixels by 2000 pixels. Moreover, a structure of data processing nodes
5 corresponding to any such image frame often as not includes hundreds or even thousands of such nodes to the extent that the readability of such a structure becomes problematic from a user's point of view when displayed as an alternative to said image frame.

A need therefore exists for a method and apparatus of processing
10 image data including a plurality of components defined by a plurality of data processing nodes, which is more intuitive to a user and allows said user to rapidly identify a relevant edit data processing node and edit the data and/or parameters therein.

15 **Brief Summary of the Invention**

According to the present invention, a method of processing image data is provided which comprises storage means, processing means and display means, wherein said image data includes a plurality of components defined by a plurality of hierarchical data processing nodes, said storage
20 means are configured to store said image data and said processing means are configured to perform the steps of
generating first image data by means of processing said hierarchical data processing nodes;
outputting said first image data to said display means;
25 restructuring said hierarchy in response to user input data; and

generating second image data by means of processing said restructured hierarchical editing nodes; and
outputting said second image data to said display means.

5 **Brief Description of the Several Views of the Drawings**

Figure 1 shows an image processing system operated by an editor;

Figure 2 details the hardware components of the image processing system of *Figure 1* in further detail;

10 *Figure 3* details the operational steps according to which a user operates the image processing system of *Figures 1* and *2*;

Figure 4 shows the contents of the main memory shown in *Figure 2* subsequently to the instructions processing start shown in *Figure 3*;

Figure 5 details the loading and processing of image data as described in *Figure 4*;

15 *Figure 6* shows the video display unit shown in *Figure 1* as displaying an image frame within the graphical user interface (GUI) of the application shown in *Figures 4* and *5*;

Figure 7 shows a process tree as an example of the main structure shown in *Figures 4* and *5*;

20 *Figure 8* provides a graphical representation of the data generated at each data processing node of the process tree shown in *Figure 7* when said processing nodes are processed;

Figure 9 further details the main structure shown in *Figures 4*, *7* and *8* in terms of hierarchically structured data processing nodes;

25 *Figure 10* shows the process tree shown in *Figures 7*, *8* and *9* within the GUI shown in *Figure 6* according to the prior art;

Figure 11 details the operational steps according to which relevant image data is identified and edited according to the present invention;

Figure 11b details the operational steps according to which sub-structures of data processing nodes are identified;

5 *Figure 11c* details the operational steps according to which an image component is selected by means of its corresponding sub-structure;

Figure 11d details the operational steps according to which compatible data processing nodes are identified and selected in a different sub-structure;

10 *Figure 12* shows the image frame within the graphical user interface (GUI) shown in *Figure 6* according to the present invention;

Figure 13 shows the process tree shown in *Figures 7, 8* and *9* within the GUI shown in *Figure 6* according to an alternative embodiment of the present invention;

15 *Figure 14* shows the image frame within the graphical user interface (GUI) shown in *Figure 12*, wherein navigation input data shown in *Figure 11* has been provided;

Figure 15 shows the process tree shown in *Figure 13* according to an alternative embodiment of the present invention, wherein navigation input data shown in *Figure 11* has been provided;

20 *Figure 16* shows the image frame within the graphical user interface (GUI) shown in *Figures 12* and *14*, wherein alternative navigation input data shown in *Figure 11* has been provided;

25 *Figure 17* shows the process tree shown in *Figures 13* and *15* according to an alternative embodiment of the present invention, wherein alternative navigation input data shown in *Figure 11* has been provided;

Written Description of the Best Mode for Carrying Out the Invention

Figure 1

5 An image processing system such as a post-production station is illustrated in *Figure 1*. A processing system **102**, such as an Octane™ produced by Silicon Graphics Inc., supplies image signals to a video display unit **103**. Moving image data is stored on a redundant array of inexpensive discs (RAID) **104**. The RAID is configured in such a way as to store a large
10 volume of data, and to supply this data at a high bandwidth, when required, to the processing system **102**. The operator controls the processing environment formed by the processing system **102**, the video monitor **103** and the RAID **104**, by means of a keyboard **105**, and a stylus-operated graphics tablet or a mouse **106**. The processing system shown in *Figure 1*
15 is optimal for the purpose of processing image and other high bandwidth data. In such a system, the instructions for controlling the processing system are complex. The invention relates to any computer system where processing instructions are of significant complexity.

 Instructions controlling the processing system **102** may be installed
20 from a physical medium such as a CDROM or DVD disk **107**, or over a network **108**, including the Internet. These instructions enable the processing system **102** to interpret user commands from the keyboard **105** and the graphics tablet **106**, such that image data, and other data, may be viewed, edited and processed.

Figure 2

The processing system 102 shown in *Figure 1* is detailed in *Figure 2*. The processing system comprises two central processing units 201 and 202 operating in parallel. Each of these processors is a MIPS R11000 manufactured by MIPS Technologies Incorporated, of Mountain View, California. Each of these processors 201 and 202 has a dedicated secondary cache memory 203 and 204 that facilitate per-CPU storage of frequently used instructions and data. Each CPU 201 and 202 further includes separate primary instruction and data cache memory circuits on the same chip, thereby facilitating a further level of processing improvement. A memory controller 205 provides a common connection between the processors 201 and 202 and a main memory 206. The main memory 206 comprises two gigabytes of dynamic RAM.

The memory controller 205 further facilitates connectivity between the aforementioned components of the processing system 102 and a high bandwidth non-blocking crossbar switch 207. The switch makes it possible to provide a direct high capacity connection between any of several attached circuits. These include a graphics card 208. The graphics card 208 generally receives instructions from the processors 201 and 202 to perform various types of graphical image rendering processes, resulting in images, clips and scenes being rendered in real time on the monitor 102. A high bandwidth SCSI bridge 209 provides an interface to the RAID 104, and also, optionally, to a digital tape device, for use as backup.

A second SCSI bridge 210 facilitates connection between the crossbar switch 207 and a DVD/CDROM drive 211. The DVD drive provides a convenient way of receiving large quantities of instructions and

data, and is typically used to install instructions for the processing system 101 onto a hard disk drive 212. Once installed, instructions located on the hard disk drive 212 may be fetched into main memory 206 and then executed by the processors 201 and 202. An input output (I/O) bridge 213 provides an interface for the graphics tablet 106 and the keyboard 105, through which the user is able to provide instructions to the processing system 102.

Figure 3

Terminal 102 is switched on by user 101 at step 301, such that central processing unit instructions may be permanently loaded onto hard disk drive 212 or temporarily loaded within main memory 206 from CD ROM or DVD ROM 107, network server 109 or the Internet 108.

Upon completing the loading operation of step 302, the application starts at step 303, whereby the instructions thereof are processed by central processing units 201 and 202. At step 304, image data from a single frame or, alternatively, from a clip of frames is acquired from frame store 104 such that it can be displayed to user 101 on video display unit 103 for subsequent editing at step 305.

Upon observing the frame displayed at step 304, user 101 is thus at liberty to modify any or all of the various components of the image data at step 305. The final edited image data may eventually be stored at frame store 104 upon completing the required level of image data editing.

At step 307, a question is asked as to whether another image frame or another clip of image frames require processing by image processing system 102, whereby control is returned to step 304 such that a new frame

or clip of frames can be acquired from frame store 104 if answered in the affirmative. Alternatively, if the question asked at step 307 is answered in the negative then user 101 is at liberty to eventually switch the image processing system 102 off at step 308.

5 The contents of main memory 206 subsequent to the instructions processing start of step 303 and image data acquisition of step 304 are further detailed in *Figure 4*.

Figure 4

10 An operating system is shown at 401 which comprises a reduced set of instructions for CPUs 201 and 202, the purpose of which is to provide image processing system 102 with basic functionality. Examples of basic functions include access to files stored on hard disk drive 212 or DVD/CD ROM drive 211 and management thereof, network connectivity with frame
15 store 104, server 109 and the Internet 108, interpretation and processing of the input from keyboard 105 and graphic tablet or mouse 106 and graphical data or binary data output. In the example, the operating system is IRIX™ provided by Silicon Graphics Inc, but it will be apparent to those skilled in the art that the instructions according to the present invention may be easily
20 adapted to function under different other known operating systems, such as Windows™ provided by the Microsoft Corporation of Redmond, California or LINUX which is freely distributed.

 An application is shown at 402 which comprises the instructions loaded at step 302 that enable the image processing system 102 to perform
25 steps 303 to 307 according to the invention within a specific graphical user interface displayed on VDU 103.

Application data is shown at 403 and comprises various sets of user input dependent data and user input independent data according to which the application shown at 402 processes image data. Said application data primarily includes main structure data 404, which references the entire history of the image data as loaded at step 304 and comprehensively defines each component within an image frame in terms of hierarchically-structured data processing nodes, an example of which will be described further below. Accordingly, application data 403 also includes data 405 defining the various types of data processing nodes present within the structure or which may be inserted therein as a consequence of image data editing.

Further to the main structure data 404 and nodes definition data 405, application data 403 includes node data 406 to 411 to be processed in order to generate the current image frame, i.e. the parameters and data which, when processed by their respective data processing nodes, generate the various components of said image frame.

In the example, node data comprises three-dimensional models 406 defined as a plurality of polygons or possibly non-uniform rational B-splines (NURBS). Node data also comprises bitmap files 407 to be applied as textures to said three-dimensional models 406 lightmaps 408 wholly or partially.

Node data also comprises three-dimensional positional data 409, possibly in the form of vectors, to define scaling and tracking of said three-dimensional models 406 within a three-dimensional space. Node data also comprises RGB data 410 defining an image frame derived from film and digitally stored in frame store 104. Node data eventually comprises sound

files 411, for instance the portion of clip soundtrack corresponding to the image frame being edited. It will be easily understood by those skilled in the art that the above data types are for illustrative purposes only and the list described is non-exhaustive. Said data types relate to the type of data processing nodes required to define and generate the image frame components, a potentially infinite combination of which there may exist.

Frame data is shown at 412, which comprises user input independent data defining image frames acquired from frame store 104. Said definition includes a ClipID 413 referencing which clip a frame to be edited is part of and a FrameID 414 referencing which frame is to be edited within said clip. Frame data 412 also includes frame resolution 415 indicating the frame size in terms of picture screen elements, known to those skilled in the art as pixels, such that application 402 may appropriately configure output data for display at full resolution.

Finally, user input data is shown at 416, which comprises user input dependent data identifying parameters and/or data input by user 101 by means of keyboard 105 and graphic tablet or mouse 106 for the purpose of editing the above image data.

Figure 5

The loading and processing of image data as described in Figure 4 at step 304 is further detailed in Figure 5.

Initially, the main structure 404 is loaded at step 501, whereby all of the data processing nodes are initiated, along with node type data 405 and node data 406 to 411. At step 502, said data processing nodes are processed according to the hierarchy defined by said main structure,

whereby all of the data processing nodes process their respective node data 406 to 411. The totality of image components defined by said main structure 404 are thus output to VDU display 103 as an image frame for user 101 to subsequently edit at step 503.

5 A question is asked at step 504 as to whether a new image component is required. User 101 may wish to impart some creative input to the image frame as it is currently defined, for instance by means of new visual effects or further objects within the scene defined by said image frame. If the question is answered in the affirmative, a data processing
10 node is initiated at step 505.

In the preferred embodiment of the present invention, said node may either already have been initiated according to step 501 or may be a new type of application-compatible node loaded ed from CD ROM or DVD ROM 107 or network server 109 or downloaded from the Internet 108. Upon
15 completing the initiation step 505, the new data processing node is registered within the main structure 404 at step 506, in terms of its dependency with regard to all of the other data processing nodes already referenced therein, a more detailed description of which will be provided further below. Alternatively, the question of step 504 is answered
20 negatively, whereby image data can now be edited according to step 305.

Figure 6

The image frame generated according to step 502 for display according to step 503 is preferably output to the video display unit 103 of
25 image processing system 102, within a Graphical User Interface (GUI), which is shown in *Figure 6*.

The GUI 601 of application 502 is divided into a plurality of functional areas, portions of which are user-operable. A first area 602 displays image data 603 acquired at step 304. A second area 604 comprises user-operable conventional clip navigation widgets allowing user 101 to rewind 605, backward play 606, pause 607, stop 608, forward play 609 or fast-forward 610 the sequential order of image frames within a clip if user 101 acquired a clip at step 304.

A counter area 611 is provided in close proximity to area 602 and divided into an hour counter 612, minute counter 613, seconds counter 614 and frame counter 615, whereby said frame counter may operate in base twenty-four, base thirty or base sixty depending upon the provenance of the clip, eg respectively cinema, video or high definition TV. Said counter area 611 enables user 101 to accurately determine where the currently displayed image frame is located within the complete sequence of the clip.

A user-operable switch 616 is also provided within GUI 601, the manipulation of which by user 101 via preferably but not exclusively, mouse 106 allows GUI 601 to alternatively display the image frame 603 or a graphical representation of the corresponding main structure 404 defining the components thereof.

A user-operable conventional bar 617 of menu commands is provided in the left uppermost area of GUI 601, which includes a plurality of shortcuts to facilitate frame or file access, application configuring and other such conventional application functions. A user-operable conventional bar 618 of GUI sizing or application termination icons are provided in the right uppermost corner of 601.

In the example, user 101 acquires image data 403 and 412 defining image frame 603 from frame store 104 according to step 304, whereby the components thereof are displayed in display area 602 of GUI 601 according to step 503.

6

Figure 7

A simplified example of a main structure 404 defining the components of image frame 603, also known to those skilled in the art as an edit decision list or process tree, is shown in *Figure 7*.

10

15

20

25

A process tree consists of hierarchical, sequentially-linked data processing nodes, each of which specifies a particular processing task required in order to eventually achieve scene output data 701, for instance under the form of frame 603. Traditionally, an output sequence 701 will comprise both image data and audio data. Accordingly, the scene will thus require the output from an image-keying node 702 and the output of a sound mixing node 703. The image-keying node 702 calls on a plurality of further graphic data processing nodes to obtain all of the input data it requires to generate the desired image components. In effect, all of the nodes in the process tree define 'branches' of parent and children nodes and sub-divisions thereof and, insofar as the graphical nodes of the tree shown in *Figure 7* are concerned, each branch of nodes born from the ultimate graphical parent node 702 defines a layer. The purpose of image-keying node 702 is thus to composite the layers, e.g. superimpose the four layers shown in the example, which are further detailed below.

In the example, the desired output image frame includes a three-dimensional computer generated object composited with a background also

consisting of a plurality of three-dimensional objects superimposed over a background texture.

The image-keying node 702 thus initially requires a frame as RGB data 410 from frame node 704, which is subsequently processed by a colour-correction processing node 705 and subjected to positional data 709 of a motion tracking processing node 706. The composited three-dimensional model 406 generated by three-dimensional modelling node 707, to which is applied a bitmap file 407 as a texture by the texturing node 708 and appropriate lightmap 408 by artificial light processing node 709, is scaled by scaling node 710 and also subjected to positional data 709 of a motion tracking processing node 711, such that it is seamlessly composited within the colour corrected frame 704.

In so far as the background is concerned, the image keying processing node 702 also requires a uniform texture 407 from a texturing node 712, the functionality of which is similar to the texturing node 708, to which is applied the colour-correction of a colour-correction processing node 713, the functionality of which is similar to node 705. The image-keying processing node 702 finally requires to overlay the plurality of simple three-dimensional models 406 generated from the three-dimensional modelling node 714, which are appropriately lit with lightmaps 408 by the artificial light processing node 715 and motion-tracked with positional data 409 by means of the motion-tracking processing node 716 over the colour corrected-texture 711 before overlaying the composited frame of node 704 on top of the composited background. The scene 701 is completed by associating the output of sound mixing node 703 with the output of image keying node 702.

Figure 8

5 It is common for process trees such as detailed in *Figure 7* to incorporate hundreds and potentially even thousands of logically-linked data processing nodes configured as parent processing nodes and children processing nodes, each of which symbolises a functionality applied to some form of data or other.

10 The respective output data of each parent and children nodes 701 to 716 of the process tree detailed in *Figure 7* are graphically shown in *Figure 8* in order to illustrate the application data 403 processed at step 502.

15 The generation of all of the image components requires processing of all of the data processing nodes within the process tree. Said processing begins at the leftmost last child node 704, whereby an operational function of said child node 704 is invoked in order to fetch a frame 801, which depicts a real plane photographed in front of a blue or green background in order to facilitate subsequent keying processes, depending upon whether the image was respectively shot for video or cinematography.

20 Node 705 is a parent node of node 704 and subsequently pulls the frame 801 from node 704, and its colour correction operational function modifies the colour 802 of said frame by applying a processing rule to the RGB values of every pixel in said frame. According to the invention, it is known to parent node 705 that frame 801 comprises a finite number of pixels corresponding to the resolution of frame 801 as the definition 412 of the frame is an array of pixels and its resolution 415 is for instance the
25 number of pixels in a 24D high-definition cinematographic frame. The

parent node 706 of node 705 subsequently pulls the data of said node and calls an operational function designed to orient the colour-corrected frame within a three dimensional volume 803.

5 The next branch, or layer, depending from the parent node 702 is followed and thus proceeds to node 707, whereby a three dimensional computer generated model 406 of a plane is generated as component 804 by operational functions of said node 707. Its parent node 708 subsequently pulls said three-dimensional computer-generated model 804 in order to apply a "steel" bitmap texture 805 to each polygon of said three-
10 dimensional model. It is known to node 708 that the three-dimensional model is composed of polygons defined by tessellating the smallest component of the model, which are vertices.

Processing node 709 subsequently applies an artificial lighting algorithm 408 at 806 to the textured three-dimensional model and
15 processing node 710 can subsequently scale the lit (806), textured (805) three-dimensional model 804 at 807. The parent node 711 of node 710 subsequently pulls the data of said node and calls an operational function designed to animate the the composited plane 807 within a three dimensional volume 808, known to those skilled in the art as motion-
20 tracking.

With respect to the topmost graphical parent node 702 within the process tree, two further branches respectively defined by nodes 712, 713 and 714 to 716 have to be processed before it pulls the input data and processes said data itself. A "sky" bitmap texture 809 is thus generated by
25 node 712 which is subsequently colour-corrected at parent node 713 using the same operational function as was invoked by colour-correction

processing node 705 to process the frame 801.

Similarly, a computer-generated three-dimensional "clouds" model 811 is generated by node 714 utilising potentially the same operational function as was invoked by node 707 to generate the "plane" three dimensional model. The three-dimensional model 811 is subsequently lit (812) at parent node 715 using potentially the same lighting algorithm of the operational function called at node 709. The lit (812) three-dimensional model 810 is subsequently motion-tracked (813) at processing node 716 utilising the same operational functions invoked by processing nodes 706, 711 in order to eventually match the motion of the real and composited planes with the composited clouds.

Upon completing the processing 813 at node 716, the parent node 702 is thus able to pull all of the input data 801 to 813 and process it in order to generate a composite frame 814 comprising three elements, within which two planes appear superimposed over a sky and clouds. Sound data 815 will then be processed by node 703, whereby output node 701 outputs final graphic data 814 and sound data 815 as an image frame 816.

Figure 9

The main structure data 404 shown in *Figure 4* and further illustrated in *Figure 7* is shown in greater detail in *Figure 9* to better describe the hierarchy of data processing nodes it comprises as shown in *Figures 7 and 8*.

In the preferred embodiment of the present invention, each data processing node is referenced with a node ID 901 and is referenced as either a parent node 902, a child node 903 or a combination thereof, as the case maybe. Each data processing node is further referenced by means of its type

data 405 at 904 and its function specific input data type 406 to 411 is similarly referenced at 905.

The main structure 404 shown in *Figure 9* takes the form of a database for illustrative purposes only, as it will be apparent to those skilled in the art that any other referencing structure providing for the hierarchical structuring of data processing nodes is suitable.

In the preferred embodiment, the node ID 901 is generated during the first processing step 502 according to the processing order outlined in *Figures 7* and *8*, whereby the parent dependencies 902 and children dependencies 903 of each data processing nodes are generated and subsequently updated in real-time. Thus, in the example, the first node accessed at processing step 502 is the scene node 701 to which a node ID 906 is affixed. The next processing node accessed at said processing step 502 is data processing node 702 to which node ID 907 is affixed.

Data processing node 702 is a child node of data processing node 701, whereby the parent dependency 908 of said parent node 701 is updated and the child dependency 909 of said data processing node 702 is similarly updated.

Thus, for each subsequent data processing node sequentially accessed during said processing step 502, a new node ID is provided and the respective parent dependencies and child dependencies updated according to the principle outlined above, as are the corresponding node type 904 and node data type 905 populated, until such time as the entire main structure, or process tree, have been processed once. In the preferred embodiment of the present invention, one such processing cycle takes place within one thirtieth of a second.

Figure 10

Upon completing the processing step 502 and thus the registration of the parent and children data processing nodes as shown in *Figure 9* in order to establish their hierarchy, image data processing system 102 can provide a graphical representation of the image frame 603 in terms of a hierarchy of data processing nodes, which is shown in *Figure 10*.

In the example, user 101 provides first user input data 416 to the effect of activating user-operable switch 616, the processing of which instructs image data processing system 102 to alternate the display mode in display area 602 from frame display mode to structure display 1001, whereby said user operable switch 616 also alternates to user operable switch 1002 which, when activated, alternates said structure display 1001 back to frame display 602, wherein data processing nodes 701 to 716 are processed to display rendered image components according to steps 502, 503.

In the example, the activation of user operable switch 616 generates structure display 1001, whereby the entire main structure 404 is graphically represented, thus including data processing nodes 701 to 716 as a hierarchical structure of logically-linked data processing nodes, preferably but not necessary including a graphical representation of their corresponding respective output data 801 to 816.

The method and apparatus as described above will so far be familiar to those skilled in the art, especially post-production image processing specialists. Said specialists will thus appreciate that the structure shown in *Figures 7, 8 and 10* is herein kept to an overly simplistic scale for the purpose of clarity in the present description as compared to traditional structures

comprising at the very least hundreds of such hierarchically structured data processing nodes. Consequently, said specialists will be well aware of the inherent difficulty in intuitively and rapidly identifying a particular data processing node, the parameters and/or data of which require editing, for instance to remove artefacts visible in image frame 603, implement additional effects and/or components (such as add a third plane) or, more generally, simply to adjust the overall appearance of image frame 603 for aesthetic considerations.

According to the prior art, user 101 would activate the user operable switch 616 and thus be presented with the entire structure 404 defining image frame 603 as depicted within display area 1001. User 101 would then have to firstly be familiar with the main structure 404 and its operating principle as described in *Figures 7 and 8*. Said user 101 would then have to identify the actual data processing nodes, the parameters and/or data of which require editing, from amongst all of said data processing nodes. Upon eventually identifying said relevant data processing node, said user would then select said node and amend the parameters and/or data thereof.

Thus, according to the known prior art, if user 101 needs to edit the positional data 409 processed by tracking node 711 in order to improve the motion of what is initially a three-dimensional model 804 within frame 603, user 101 would have to identify and subsequently select said node 711 within structure 404 as displayed in GUI area 1001.

Similarly, if user 101 needs to modify the artificial lighting applied to said model 804 at lighting node 709 using a light map 408, user 101 would need to identify and subsequently select said lighting node 709 within the main structure 404 as shown in GUI area 1001. It can thus be appreciated

that in an apparatus configured to the known prior art, or when using a method according to the known prior art, identifying and selecting a relevant data processing node from amongst hundreds or, more realistically, thousands of such logically-linked data processing nodes is unintuitive and time-consuming. Modern requirements for ever-more sophisticated effects applied to talents or environments or objects within a frame such as frame 603 compound the above problem, insofar as said effects require an ever increasing amount of varied data processing nodes.

10 **Figure 11**

The present invention remedies the above problem by providing a method of intuitively identifying and selecting any data processing node within main structure 404 with selectively culling parent dependencies 902 and children dependencies 903. The processing steps according to which image data is edited at step 305 according to the present invention are further detailed in *Figure 11*.

15 In the example, user 101 is a post-production image editing specialist and wishes to improve the motion of the second background plane within frame 603, initially generated from a three-dimensional model 406 together with its artificial lighting generated from a light map 408. According to the invention, at step 1101 user 101 selects said second plane as an image component within image frame 603 within GUI 602, whereby corresponding first user input data 416 is received and image processing application 402 firstly identifies all of the data processing nodes as sub-structures, e.g. layers within main structure 404. First user input data 416 is then processed such that the image component of choice is selected at step 1102.

According to the preferred embodiment of the invention, although user 101 in effect selects any which one of the plurality of data processing nodes, the processing of which generates said second plane within image frame 803, it is irrelevant which specific data processing node within said sub-group is selected as application 402 eventually selects the first data processing node at step 1103 within the data processing node sub-structure identified at step 1102.

In effect, at said step 1102, application 402 identifies the last parent node of only the layer defining the image component selected at step 1101, e.g. the first data processing node which defines a new layer or sub-structure after the keyer node 702. In the example, said last data processing node is tracking node 711.

A question is asked at the next step 1104 as to whether navigation input data has been received, i.e. whether application 402 has received further user input data 416 indicative of a decision that the data processing node 711 as selected at step 1103 is not the data processing node required for editing. In the preferred embodiment of the present invention, said navigation input data is provided by means of specific keystroke on keyboard 105 or mouse button activation on mouse 106, but it will be apparent to those skilled in the art that any type of binary input device is appropriate to generate such navigation input data.

If the question of step 1104 is answered positively, a second question is asked at step 1105 as to whether the navigation input data received corresponds to linear navigating amongst parent and children nodes of a same layer, as first selected at step 1102, or if it corresponds to transversal navigating amongst compatible children nodes of a different layer, whereby

said nodes are referred to as siblings.

5 If the question asked at step 1105 is answered positively, the next data processing node in the sub-structure identified at step 502 is selected at step 1107 which, in the example, is the scaling node 710. Alternatively, the question asked at step 1105 is answered negatively, whereby a sibling is identified at step 1106 in a different sub-structure and control returned to question 1104, such that navigation within said different sub-structure and node selection therein is now possible.

10 When the question asked at step 1104 is eventually answered negatively, a third question is asked at step 1108 as to whether application 402 has received selection input data. Said selection input data is again user input data 416 but differs from the navigation input data of question 1104 in that it is processed by application 402 for updating application data 406 to 411 to be processed by the data processing node selected at step 502. Said selection input data is again read from keyboard 105 or mouse 106, or a combination thereof but question 1108 is only answered positively if said input data differs from the pre-set navigation input data of questions 1104, e.g. input data read at question 1108 differs from the keystroke or mouse click input to effect navigation at question 1104.

20 Thus, when question 1108 is answered positively, the editing of parameters and/or data is initiated at step 1109 for the data processing node selected at step 1107, and the edited image data may eventually be stored according to step 306. Alternatively, question 1108 is answered negatively whereby the edited image data may immediately be stored according to step 25 306.

Figure 11b

The operational steps according to which sub-structures of data processing nodes are identified at step 1101 are further described in *Figure 11b*. At step 1111, recurring child node references are identified within the main structure as repeated occurrences of the dependency of a data processing node on a parent data processing node. Thus, in the example, the first level of substructural division is based upon the dependency of image keying node 702 shown at 907 with a child node reference 909 and sound mixing node 703 with a node ID 901 equal to 0016 and an identical child node reference equal to 0001 respectively children of seen output node 701 shown at 906.

Further in the example, the editor is only concerned with image data and thus the next level of substructural division is attained by identifying the recurring graphic child node reference 903 equal to 0002.

Upon completing the above identification step, a boundary is set for each substructure, or layer, at step 1112 based upon said identified recurring graphic child node reference, whereby a precise identification of each substructure presence within main structure 404 is made possible and accomplished at step 1113. Referring back to *Figure 9*, four substructures each defining a separate image component are identified, the respective first parent node of which are tracking node 706 (node ID 0003), tracking node 711 (node ID 0006), colour correction node 713 (node ID 0011) and tracking node 716 (node ID 0013).

Figure 11c

The operational steps according to which an image component is selected by means of its corresponding sub-structure at step 1102 are further described in *Figure 11c*. At step 1121, the X, Y input data 416 read at step 1101 is processed in order to identify which substructure defines the selected image component. It was previously explained at that the precise identification of a specific data processing node within the substructure is irrelevant as it is the ultimate parent node within the substructure which is eventually selected by means of processing the nodes dependencies within said substructure. Thus, as the X, Y input data 416 is processed to identify a specific node, its ultimate parent node is eventually identified as shown at 1121, wherein in the example the lighting node 709 (node ID 0008) is derived from said input data processing, its dependencies processed and its ultimate parent node tracking node 711 (node ID 0006) selected thus identifying the selected image component as belonging to layer two.

Upon completing the above identification step, all of the data processing nodes of the identified substructure are selected to the exclusion of any other data processing node belonging to other substructures.

Figure 11d

The operational steps according to which compatible data processing nodes are identified and selected in a different sub-structure at step 1106 are further described in *Figure 11d*. At step 1131, the node type 904 of the data processing nodes selected at step 1107 is read in main structure 404 and the next substructure is selected at step 1132, preferably by identifying the ultimate parent node of the current substructure and

identifying the ultimate parent node of the next substructure.

At step 1133, the equivalent data processing node is selected in the new layer selected at step 1132, preferably by means of processing the same number of dependencies, whereby the respective node type 904 of the initial data processing node read at step 1131 and the sibling data processing node read at step 1133 are compared for type match at step 1134. A question is subsequently asked at step 1135 in order to determine if said respective mode types 904 match. If the question of step 1135 is answered negatively, the next dependant node will be selected at step 1133 for node type matching at step 1134, for instance if various other functionality's are invoked by means of data processing nodes with a different node type between the substructure defining node and the sibling node in said next layer. The question of step 1135 is eventually answered positively, whereby control returns to the question of step 1104, e.g. whether navigation input data has been received or not.

Figure 12

The graphical user interface 601 of application 402 is shown in *Figure 12*, wherein user 101 has selected the second plane as an image component of image frame 603 according to step 1101.

In the preferred embodiment of the present invention, the data processing nodes 707, 708, 709 and 711 are identified at step 1101 as the sub-structure of nodes generating the second plane as an image component of image frame 603 and the tracking node 711 is selected as the ultimate processing node applied to said image component according to step 1103.

Consequently, until such time as application 402 receives either navigation input data, the effect of which would be to select the next node 710 within said sub-structure, or selection input data, the effect of which would be to initiate the editing of the current parameters and/or data of tracking node 711, a graphical representation of said parameters and data specific to the functionality of the current selected node 711 is provided within image data 603. Said representation includes a vector 1201, the direction of which depicts the direction of travel of the plane within a reference three-dimensional space 1202 and the length of which depicts the velocity of said plane.

A three-dimensional cubic volume 1203 encompasses the plane within said three-dimensional reference space 1202 to depict more intuitively the offset angle between the relative floor of space 1202 as defined by abscissas X and Z and the wing span of the three-dimensional model corresponding to said plane.

According to the invention, navigation user input data may now be provided as an answer to question 1104, preferably within the same sub-structure as an answer to question 1105, whereby parameters and data combinations 1201 to 1203 specifically relating to the functionality of tracking node 711 would be replaced by graphical representation of parameters and data combinations specific to the next data processing structure 710, ie specific to the editing of parameters and/or data relating to the scaling of the plane within the reference three-dimensional space 1202 and so on and so forth until the process selects the last child node 707 within said sub-structure, whereby editing of parameters and/or data could for instance include the generation of a completely different type of plane as an

alternative three-dimensional model 406.

Figure 13

According to another preferred embodiment of the present invention,
5 the user 101 of image processing system 102 configured according to the
invention may prefer to edit the parameters and/or data graphically
represented at 1201 to 1203 in more detail than can be perceived as
graphically depicted in GUI 601 as shown in *Figure 12* and thus application
402 may receive user input data 416 to the effect that the user operable
10 switch 616 is activated such that the sub-structure of data processing nodes
identified according to step 1102 is displayed within structure display area
1001. A graphical representation of said structure display area 1001
configured according to the present invention is shown in *Figure 13*.

In the example, user 101 selects the second plane as described in
15 *Figure 12* but subsequently activates user operable switch 616 before
inputting navigation input data according to question 1104 or selection input
data according to question 1108, whereby frame display area 602 alternates
to structure display area 1001 and said user operable switch 616 alternates
to user operable switch 1002. The main structure 404 is culled according to
20 step 1122 and the ultimate data processing node is selected in the sub-
structure of data processing nodes defining said selected second plane,
whereby only said sub-structure is graphically displayed at 1301, which only
comprises data processing nodes 711 to 707 in accordance with the example
previously described in *Figure 12*.

25 In the alternative preferred embodiment, the selected first data
processing node 711 is highlighted such that image editor 101 is immediately

made aware of which type of parameters and/or data he may initiate the editing thereof according to step 1109. Said data processing node highlighting is provided here only as an example and it will be readily apparent to those skilled in the art that any other alternative providing a similar functionality is here envisaged.

5 In the alternative embodiment still, application 402 generates a parameters and data display area 1302 corresponding to said selected data processing node which, in the example is tracking node 711. Depending upon the processing functionality provided by said selective node, said parameters and data display area 1302 may vary to a large extent. Preferably, area 1302 clearly identifies tracking node 711 by means of its corresponding node type data 405 referenced at 904, as well as its various parameters 1303 and parameter data 1304.

10 In the alternative preferred embodiment of the present invention, user 101 may input selection input data according to question 1108 within parameter data 1304, within which data corresponding to graphical representations 1201 to 1203 are shown for the purpose of clarity. Application 402 may at any time receive user input data 416 to the effect of either editing parameter 1303 and/or parameter data 1304, or to the effect of navigating further within sub-structure 1301 in accordance with processing steps described in Figure 11, or to the effect that user operable switch 1002 has been activated and this alternates structure display area 1001 back to image frame display area 602, the generation of the image components of which would thus incorporate any editing implemented within parameters 1303 and/or parameter data 1304.

Figure 14

The graphical user interface 601 of application 402 is shown in Figure 14, wherein user 101 has selected the second plane as an image component of image frame 603 according to step 1101 and subsequently provided application 402 with navigation input data according to question 1104 in order to edit the lighting data of lighting node 709.

It was previously explained that the data processing nodes 707, 708, 709, 710 and 711 are identified at step 1101 as the sub-structure of nodes generating the second plane as an image component of image frame 603 and the tracking node 711 is selected as the ultimate processing node applied to said image component according to step 1103.

Consequently, when application 402 receives navigation input data, the effect of which is to select the next node 709 within said sub-structure, a graphical representation of said parameters and data specific to the functionality of the current selected node 709 is provided within image data 603. Said representation includes a spotlight 1401 indicative of the type of lightmap 408 said second plane is processed with. Said representation also includes a focus area 1402 and corresponding light cone 1403 respectively depicting the focus of spotlight 1401 and the lighting energy provided thereto, within the reference three-dimensional space 1202. Finally, said representation includes a user-operable colour selector 1404 with which to intuitively select appropriate RGB colour data for said lightmap. User 101 has therefore rapidly identified the relevant data processing node and may now input selection input data according to steps 1108 and 1109, thus intuitively editing parameters and/or data to be processed by the selected lighting node

709 to improve the characteristics of the selected image component.

Figure 15

According to another preferred embodiment of the present invention,
5 the user 101 of image processing system 102 configured according to the
invention may prefer to edit the parameters and/or data graphically
represented at 1401 to 1404 in more detail than can be perceived as
graphically depicted in *Figure 14* and thus application 402 may receive user
input data 416 to the effect that the user operable switch 616 is activated
10 such that the sub-structure of data processing nodes identified according to
step 1101 is displayed within structure display area 1001. A graphical
representation of the structure display area 1001 depicting the image data
editing shown in *Figure 14* is shown in *Figure 15*.

In the example, user 101 again selects the second plane as described
15 in *Figure 12* but subsequently activates user operable switch 616 before
inputting navigation input data according to question 1104, whereby frame
display area 602 again alternates to structure display area 1001 and said
user operable switch 616 alternates to user operable switch 1002. The main
structure 404 is culled according to step 1122 and the ultimate data
20 processing node is selected in the sub-structure of data processing nodes
defining said selected second plane, whereby only said sub-structure is
graphically displayed at 1501, which only comprises data processing nodes
707 to 711 in accordance with the example previously described.

In the alternative embodiment, the selected last data processing node
25 711 is highlighted such that image editor 101 is immediately made aware of
which type of parameters and/or data he may initiate the editing thereof

according to step 1109. User 101 however wishes to edit the parameter data of lighting node 709 and thus provides application 402 with navigation input data at 1104 until such time as said data processing node 709 is highlighted.

In the alternative preferred embodiment still, application 402 again generates a parameters and data display area 1302 corresponding to said selected data processing node 709. As the processing functionality provided by said selected node differs from the processing functionality of node 711, said parameters and data display area 1302 vary to a large extent relative to that shown in *Figure 13*. Preferably, area 1302 clearly identifies tracking node 709 by means of its corresponding node type data 405 referenced at 904, as well as its various parameters 1502 and parameter data 1503.

In the alternative preferred embodiment of the present invention, user 101 may input selection input data according to question 1108 within parameter data 1503, within which data corresponding to graphical representations 1401 to 1404 are shown for the purpose of clarity. Application 402 may at any time receive user input data 416 to the effect of either editing parameters 1502 and/or parameter data 1503, or to the effect of further navigating within sub-structure 1501 in accordance with processing steps described in *Figures 11 to 14*, or to the effect that user operable switch 1002 has been activated and this alternates structure display area 1001 back to image frame display area 602, the generation of the image components of which would thus incorporate any parameters and/or data editing implemented within parameters 1502 and/or parameter data 1503.

Figure 16

The graphical user interface **601** of application **402** is shown in *Figure 16*, wherein user **101** has selected the tracking node **706** eventually applied to frame data **801** as a sibling of tracking node **711** eventually applied to 3D model data **804**, according to step **1106**.

5 The provision for transversal navigation allows the editor **101** to intuitively and rapidly edit the data and/or parameters of a plurality of data processing nodes respectively belonging to separate sub-structures, the functionality of which is comparable. In the example, editor **101** has edited parameter data **1304** processed by tracking node **711** in frame view, but now
10 wishes to edit the similar parameter data processed by tracking node **706** to fine-tune the relative positioning between the film-based plane and the 3D-modelled plane in the output image frame. Upon accomplishing the procedural steps described in *Figure 12*, the currently selected data processing node is therefore tracking node **711**.

15 Upon inputting corresponding navigation input data **416** interpreted at question **1105** as selecting a different sub-structure, data processing node **716** is identified as the next sibling node featuring comparable data type **904** in main structure **404**, which motion-tracks the 3D-modelled clouds. But editor **101** wishes to edit data pertaining to the generation of the first plane,
20 therefore further navigation input data **416** is input to be interpreted at question **1105** as selecting a different sub-structure, whereby data processing node **706** is identified as the next sibling node featuring comparable data type **904** in main structure **404**, which orients the plane frame **801** within the three-dimensional reference space **1202**.

25 The representation of the functionality, parameters and data of tracking node **706** includes a two-dimensional plane **1601** encompassing the

frame within said three-dimensional reference space 1202 to depict more intuitively the offset angle between the relative floor of space 1202 as defined by abscisses X and Z and the frame 801. Said representation also includes a vector 1602, the direction of which depicts the direction of travel of the frame within said reference three-dimensional space 1202 and the length of which depicts the velocity of said frame.

According to the invention, navigation user input may now be provided as an answer to question 1104, whereby parameters and data combinations 1201 to 1203 specifically relating to the functionality of tracking node 706 would be replaced by graphical representation of parameters and data combinations specific to the next data processing nodes 705 or 704, ie specific to the editing of parameters and/or data relating to the colour of the frame within the reference three-dimensional space 1202 or specific to the generation of a completely different frame.

Figure 17

According to another preferred embodiment of the present invention, the user 101 of image processing system 102 configured according to the invention may prefer to edit the parameters and/or data graphically represented at 1601 and 1602 in more detail than can be perceived as graphically depicted in *Figure 16* and thus application 402 may receive user input data 416 to the effect that the user operable switch 616 is activated such that the sub-structure of data processing nodes identified according to step 1101 is displayed within structure display area 1001. A graphical representation of said structure display area 1001 configured according to the present invention is shown in *Figure 17*.

In the example, user 101 selects the second plane as described in *Figure 12* but subsequently activates user operable switch 616, whereby sub-structure 1301 is initially displayed as only comprising data processing nodes 707 to 711 in accordance with the example previously described in *Figure 13*.
5 However, user 101 wishes to select sibling node 706 as described in *Figure 16* and thus imparts navigation input data interpreted at question 1105 as navigating in a different sub-structure.

The main structure 404 is therefore eventually culled according to step 1122 when data processing node 706 is selected as heading the next sub-structure 1701 at step 1132, and further highlighted when selected as sibling because its data type is matched against the data type of node 711 according to step 1135. Image editor 101 is again immediately made aware of which type of parameters and/or data he may initiate the editing thereof according to step 1109. Moreover, image editor 101 is also immediately
10 aware that edits will be performed for a different data processing node applied to a different image component, as the displayed topography of the sub-structure has changed.
15

Application 402 again generates a parameters and data display area 1702 corresponding to said selected data processing node 706. User 101
20 may input selection input data according to question 1108 within parameter 1703, within which data 1704 corresponding to graphical representations 1601 and 1602 are shown for the purpose of clarity. Application 402 may at any time receive user input data 416 to the effect of either editing parameter parameters 1703 and/or parameter data 1704, or to the effect of navigating
25 further within sub-structure 1701 in accordance with processing steps described in *Figure 11*, or to the effect that user operable switch 1002 has

been activated and this alternates structure display area 1001 back to image frame display area 602, the generation of the image components of which would thus incorporate any editing implemented within parameters 1703 and/or parameter data 1704.

Claims:

1. Apparatus for processing image data comprising storage means, processing means and display means, wherein said image data
5 includes a plurality of components defined by a hierarchy of data processing nodes, said storage means are configured to store said image data and said processing means are configured to perform the steps of
generating first image data by means of processing said hierarchy of data processing nodes;
10 outputting said first image data to said display means;
restructuring said hierarchy in response to user input data;
generating second image data by means of processing said restructured hierarchical processing nodes; and
outputting said second image data to said display means.
15
2. Apparatus according to claim 1, wherein said hierarchy organises said data processing nodes vertically as parent nodes, children nodes and sibling nodes.
- 20 3. Apparatus according to claim 2, wherein said sibling nodes define horizontal layers within said hierarchy.
4. Apparatus according to any of claims 1 to 3, wherein said
25 user input data includes selection data indicating the selection of one or a plurality of said components.

5. Apparatus according to any of claims 1 to 3, wherein said user input data includes navigation data indicating navigation within said hierarchy or a portion thereof.

5

6. Apparatus according to claim 5, wherein said navigation is either horizontal or vertical.

10

7. Apparatus according to any of claims 1 to 6, wherein said restructuring step includes culling said hierarchy down to one or a plurality of portions thereof.

8. Apparatus according to claim 7, wherein said second image data is a representation of said portion or portions.

15

9. Apparatus according to any of claim 1 to 7, wherein said second image data is an image frame.

20

10. A method of processing image data, wherein said image data includes a plurality of components defined by a plurality of hierarchical data processing nodes, said method comprising display means and further comprising the steps of

generating first image data by means of processing said hierarchical data processing nodes;

25

outputting said first image data to said display means;

restructuring said hierarchy in response to user input data;
generating second image data by means of processing said
restructured hierarchical processing nodes; and
outputting said second image data to said display means.

5

12. A method according to claim 11, wherein said hierarchy
organises said data processing nodes vertically as parent nodes, children
nodes and sibling nodes.

10

13. A method according to claim 12, wherein said sibling nodes
define horizontal layers within said hierarchy.

15

14. A method according to any of claims 11 to 13, wherein said
user input data includes selection data indicating the selection of one or a
plurality of said components.

20

15. A method according to any of claims 11 to 13, wherein said
user input data includes navigation data indicating navigation within said
hierarchy or a portion thereof.

25

16. A method according to claim 15, wherein said navigation is
either horizontal or vertical.

17. A method according to any of claims 11 to 16, wherein said
restructuring step includes culling said hierarchy down to one or a plurality
of portions thereof.

18. A method according to claim 17, wherein said second image data is a representation of said portion or portions.

5 19. A method according to any of claim 11 to 17, wherein said second image data is an image frame.

20. A computer-readable medium having computer-readable instructions executable by a computer, such that said computer performs
10 the steps of:

generating first image data by means of processing hierarchical data processing nodes defining said image data;

outputting said first image data to display means;

restructuring said hierarchy in response to user input data;

15 generating second image data by means of processing said restructured hierarchical processing nodes; and

outputting said second image data to said display means.

20 21. A method according to claim 20, wherein said user input data includes selection data indicating the selection of one or a plurality of said components.

22. A method according to any of claim 20, wherein said user input data includes navigation data indicating navigation within said
25 hierarchy or a portion thereof.

23. A method according to any of claims 22, wherein said restructuring step includes culling said hierarchy down to one or a plurality of said portions.

5

24. A method according to claim 23, wherein said second image data is a representation of said portion or portions.

25. A method according to claim 23, wherein said second image data is an image frame.

10

26. A computer system programmed to generate image data, storage means, processing means and display means, wherein said image data includes a plurality of components defined by a plurality of hierarchical data processing nodes, said storage means are configured to store said image data and said processing means are configured to perform the steps of

15

generating first image data by means of processing said hierarchical data processing nodes;

outputting said first image data to said display means;

20

restructuring said hierarchy in response to user input data;

generating second image data by means of processing said restructured hierarchical processing nodes; and

outputting said second image data to said display means.

43

Abstract of the Disclosure**Editing Image Data**

5 An apparatus and method for processing image data 403 are provided, which comprise storage means 206, processing means 201, 202 and display means 103, wherein said image data 403 includes a plurality of components 814 defined by a plurality of hierarchical data processing nodes 404, 405, said storage means are configured to store said image data 403 and said processing means are configured to perform the steps of
10 generating first image data 1201, 1202, 1203 by means of processing said hierarchical data processing nodes 405; outputting said first image data to said display means 103; restructuring (1122) said hierarchy 404 in response to user input data; and generating second image data 1401, 1402, 1403, 1404 by means of processing said restructured hierarchical editing nodes
15 405; and outputting said second image data to said display means.
